[†] Due to difficulty growing caliciviruses in culture, molecular characterization of members of the Caliciviridae (particularly those infecting animals) has relied on RT-PCR techniques and substantial advances have been made since the 8th ICTV report. In some cases, standard nomenclature has been altered. Some searches have been modified from the standard searches in order to sample the literature as thoroughly as possible. Database entries for bovine caliciviruses may include information found via searches for any of the bovine calicivirus species, including references cited in papers found by searches.

Ephemerovirus

[Note: The 8th report of the ICTV states that Adelaide River virus and Berrimah virus have been isolated from cattle; however no primary references to this effect were found. These species have therefore not been included in the database. The reasoning here is that if evidence of cattle infection has not been documented in the literature in a genus where cattle are the primary host, evidence of human infection is unlikely to have been documented in the literature and no inference can be drawn from failure to find documentation under these circumstances.]

Deltavirus

The single virus in this genus is dependent on hepadnavirus infection for efficient replication and are therefore excluded from the database.

Hepevirus

Hepatitis E virus

[Zoonotic transmission of this virus is suspected, and viral sequences similar to those found in pigs cause of epidemic disease in some human populations. Multiple sources (including ICTV8) imply or state that the virus is endemic in human populations. We have found no rigorous epidemiological studies that illustrate that the virus is maintained in human populations independent of animal (pig) infections; however, in deference to the prevailing view we consider the virus to be maintained in humans and exclude it from the database.]
